(54) Title: POLYKETIDES AND THEIR SYNTHESIS

monensin A : R = ethyl  
monensin B : R = methyl

WO 01/68867 A1

(57) Abstract: The complete sequence of the gene cluster for the monensin type I polyketide synthase, from *S. cinnamomensis*, is provided. Thus variant polyketides containing monensin-derived elements can be genetically engineered. Furthermore there are features, e.g. a regulatory protein *mon RI*, which are of wide utility.

— with (an) indication(s) in relation to deposited biological material furnished under Rule 13bis separately from the description

For two-letter codes and other abbreviations, refer to the "Guidance Notes on Codes and Abbreviations" appearing at the beginning of each regular issue of the PCT Gazette.

POLYKETIDES AND THEIR SYNTHESIS

The present invention relates to processes and materials (including enzyme systems, nucleic acids, vectors and cultures) for preparing polyketides, particularly polyethers but including polyenes, macrolides and other polyketides by recombinant synthesis, and to the polyketides so produced, particularly novel polyketides. (N.B the term "polyketide" is being used in its conventional sense to include structures notionally derived by the reduction and/or other processing or modification of one or more Ketide units). Furthermore the invention provides the entire nucleic acid sequence of the biosynthetic gene cluster that governs the production of the ionophoric antibiotic polyether polyketide monensin in *Streptomyces cinnamonensis*, and the use of all or part of the cloned DNA first, in the specific detection of other polyether biosynthetic gene clusters; secondly in the engineering of mutant strains of *S. cinnamonensis* and of other actinomycetes which are suitable host strains for the high level production of novel recombinant polyketides; and thirdly in the provision of recombinant biosynthetic genes which lead to such novel polyketide products.

Polyketides are a large and structurally diverse

class of natural products that includes many compounds possessing antibiotic or other pharmacological properties, such as erythromycin, tetracyclines, rapamycin, avermectin, monensin, epothilones and FK506.

5 In particular, polyketides are abundantly produced by *Streptomyces* and related actinomycete bacteria. They are synthesised by the repeated stepwise condensation of acylthioesters in a manner analogous to that of fatty acid biosynthesis. The greater structural diversity found

10 among natural polyketides arises from the selection of (usually) acetate or propionate as "starter" or "extender" units; and from the differing degree of processing of the  $\beta$ -keto group observed after each condensation. Examples of processing steps include

15 reduction to  $\beta$ -hydroxyacyl-, reduction followed by dehydration to 2-enoyl-, and complete reduction to the saturated acylthioester. The stereochemical outcome of these processing steps is also specified for each cycle of chain extension. In addition, the biosynthetic

20 pathways to many polyketides involve additional enzyme-catalysed modifications which may include: methylation by O- and C-methyltransferases, hydroxylation by cytochrome P450 enzymes, other oxidation or reduction processes, and the biosynthesis and attachment of novel sugars and/or

25 deoxy sugars.

The biosynthesis of polyketides is initiated by a group of chain-forming enzymes known as polyketide synthases. Two classes of polyketide synthase (PKS) have been described in actinomycetes. One class, named Type I  
5    PKSs, represented by the PKSs for the macrolides erythromycin, oleandomycin, avermectin and rapamycin, consists of a different set or "module" of enzymes for each cycle of polyketide chain extension. (For examples see Cortés, J. *et al.* Nature (1990) 348:176-178; Donadio,  
10    S. *et al.* Science (1991) 252:675-679; Swan, D.G. *et al.* Mol. Gen. Genet. (1994) 242:358-362; MacNeil, D.J. *et al.* Gene (1992) 115:119-125; Schwecke, T. *et al.* Proc. Natl. Acad. Sci. USA (1995) 92:7839-7843.)

The term "extension module" as used herein refers to  
15    the set of contiguous domains, from a  $\beta$ -ketoacyl-ACP synthase ("KS") domain to the next acyl carrier protein ("ACP") domain, which accomplishes one cycle of polyketide chain extension. The term "loading module" is used to refer to any group of contiguous domains which  
20    accomplishes the loading of the starter unit onto the PKS and thus renders it available to the KS domain of the first extension module. The length of polyketide formed has been altered, in the case of erythromycin biosynthesis, by specific relocation using genetic  
25    engineering of the enzymatic domain of the erythromycin-

producing PKS that contains the chain releasing thioesterase/cyclase activity (Cortés J. et al. Science (1995) 268:1487-1489; Kao, C.M. et al. J. Am. Chem. Soc. (1995) 117:9105-9106).

5 In-frame deletion of the DNA encoding part of the ketoreductase domain in module 5 of the erythromycin-producing PKS (also known as 6-deoxyerythronolide B synthase, DEBS) has been shown to lead to the formation of erythromycin analogues 5,6-dideoxy-3- $\alpha$ -mycarosyl-5-  
10 oxoerythronolide B, 5,6-dideoxy-5-oxoerythronolide B and 5,6-dideoxy,6- $\beta$ -epoxy-5-oxoerythronolide B (Donadio, S. et al. Science (1991) 252:675-679). Likewise, alteration of active site residues in the enoylreductase domain of module 4 in DEBS, by genetic engineering of the  
15 corresponding PKS-encoding DNA and its introduction into *Saccharopolyspora erythraea*, led to the production of 6,7-anhydroerythromycin C (Donadio, S. et al. Proc. Natl. Acad. Sci. USA (1993) 90:7119-7123).

International Patent Application number WO 93/13663  
20 describes additional types of genetic manipulation of the DEBS genes that are capable of producing altered polyketides. However many such attempts are reported to have been unproductive (Hutchinson, C.R. and Fujii, I. Annu. Rev. Microbiol. (1995) 49:201-238, at p. 231). The  
25 complete DNA sequence of the genes from *Streptomyces*

*hygroscopicus* that encode the modular Type I PKS governing the biosynthesis of the macrocyclic immunosuppressant polyketide rapamycin has been disclosed (Schwecke, T. et al. (1995) Proc. Natl. Acad. Sci. USA 92:7839-7843). The DNA sequence is deposited in the EMBL/Genbank Database under the accession number X86780.

WO 98/01546 discloses that a PKS gene assembly (particularly of Type I) encodes a loading module which is followed by at least one extension module. The first open reading frame encodes the first multi-enzyme or cassette (DEBS1) which consists of three modules: the loading module (ery-load) and two extension modules (modules 1 and 2). The loading module comprises an acyltransferase and an acyl carrier protein. This may be contrasted with Figure 1 of WO 93/13663 (referred to above). This shows ORF1 as only two modules, the first of which is in fact both the loading module and the first extension module.

WO 98/01546 describes in general terms the production of a hybrid PKS gene assembly comprising a loading module and at least one extension module. It also describes (see also Marsden, A.F.A. et al. Science (1998) 279:199-202) construction of a hybrid PKS gene assembly by grafting the wide-specificity loading module for the avermectin-producing polyketide synthase onto the first

multi-enzyme component (DEBS1) for the erythromycin PKS in place of the normal loading module. Certain novel polyketides can be prepared using the hybrid PKS gene assembly, as described for example in WO 98/01571.

5 WO 98/01546 further describes the construction of a hybrid PKS gene assembly by grafting the loading module for the rapamycin-producing polyketide synthase onto the first multi-enzyme component (DEBS1) for the erythromycin PKS in place of the normal loading module. The loading  
10 module of the rapamycin PKS differs from the loading modules of DEBS and the avermectin PKS in that it comprises a CoA ligase domain, an enoylreductase ("ER") domain and an ACP, so that suitable organic acids including the natural starter unit 3,4-  
15 dihydroxycyclohexane carboxylic acid may be activated *in situ* on the PKS loading domain and, with or without reduction by the ER domain, transferred to the ACP for intramolecular loading of the KS of extension module 1 (Schwecke, T. et al. Proc. Natl. Acad. Sci. USA (1995)  
20 92:7839-7843). WO 98/51695 and WO 98/49315 describe additional types of genetic manipulation of the DEBS genes that are capable of producing altered polyketides.

The second class of PKS, named Type II PKSs, is represented by the synthases for aromatic compounds. Type  
25 II PKSs contain only a single set of enzymatic activities

for chain extension and these are re-used as appropriate in successive cycles (Bibb, M.J. et al. EMBO J. (1989) 8:2727-2736; Sherman, D.H. et al. EMBO J. (1989) 8:2717-2725; Fernandez-Moreno, M.A. et al. J. Biol. Chem. (1992) 267:19278-19290). The "extender" units for the Type II PKSs are usually acetate units, and the presence of specific cyclases dictates the preferred pathway for cyclisation of the completed chain into an aromatic product (Hutchinson, C.R. and Fujii, I. Ann. Rev. Microbiol. (1995) 49:201-238). Hybrid polyketides have been obtained by the introduction of cloned Type II PKS gene-containing DNA into another strain containing a different Type II PKS gene cluster, for example by introduction of DNA derived from the gene cluster for actinorhodin, a blue-pigmented polyketide from *Streptomyces coelicolor*, into an anthraquinone polyketide-producing strain of *Streptomyces galileus* (Bartel, P.L. et al. J. Bacteriol. (1990) 172:4816-4826).

The minimal number of domains required for polyketide chain extension on a Type II PKS when expressed in a *Streptomyces coelicolor* host cell (the "minimal PKS") has been defined for example in WO 95/08548 as containing the following three polypeptides which are products of the *actI* genes: firstly KS; secondly a polypeptide termed the CLF with end-to-end

amino acid sequence similarity to the KS but in which the essential active site residue of the KS, namely a cysteine residue, is substituted either by a glutamine residue or, in the case of the PKS for a spore pigment such as the *whiE* gene product (Davis, N.K. and Chater, K.F. Mol. Microbiol. (1990) 4:1679-1691) by a glutamic acid residue; and finally an ACP. The CLF has been stated (for example in WO 95/08548) to be a factor that determines the chain length of the polyketide chain that is produced by the minimal PKS. However it has been found (Shen, B. et al. J. Am. Chem. Soc. (1995) 117:6811-6821) that when the CLF for the octaketide actinorhodin is used to replace the CLF for the decaketide tetracenomycin in host cells of *Streptomyces glaucescens*, the polyketide product is not found to be altered from a decaketide to an octaketide, so the exact role of the CLF remains unclear. An alternative nomenclature has been proposed in which KS is designated KS $\alpha$  and CLF is designated KS $\beta$ , to reflect this lack of knowledge (Meurer, G. et al. Chemistry & Biology (1997) 4:433-443). The mechanism by which acetate starter units and acetate extender units are loaded onto the Type II PKS is not known, but it is speculated that the malonyl-CoA: ACP acyltransferase of the fatty acid synthase of the host cell can fulfil the same function for the Type II PKS (Revill, W.P. et al. J.

Bacteriol. (1995) 177:3946-3952).

WO 95/08548 describes the replacement of actinorhodin PKS genes by heterologous DNA from other Type II PKS gene clusters, to obtain hybrid polyketides.

5 It also describes the construction of a strain of *Streptomyces coelicolor* which substantially lacks the native gene cluster for actinorhodin, and the use in that strain of a plasmid vector pRM5 derived from the low-copy number vector SCP2\* isolated from *Streptomyces coelicolor*

10 (Bibb, M.J. and Hopwood, D.A. J. Gen. Microbiol. (1981) 126:427-442) and in which heterologous PKS-encoding DNA may be expressed under the control of the divergent *actI/actIII* promoter region of the actinorhodin gene cluster (Fernandez-Moreno, M.A. et al. J. Biol. Chem. (1992)

15 267:19278-19290). The plasmid pRM5 also contains DNA from the actinorhodin biosynthetic gene cluster encoding the gene for a specific activator protein, ActII-orf4. The ActII-orf4 protein is required for transcription of the genes placed under the control of the *actI/actIII*

20 bidirectional promoter and activates gene expression during the transition from growth to stationary phase in the vegetative mycelium (Hallam, S.E. et al. Gene (1988) 74:305-320).

Type II clusters in *Streptomyces* are known to be

25 activated by pathway-specific activator genes (Narva,

K.E. and Feitelson, J.S. J. Bacteriol. (1990) 172:326-333; Stutzman-Engwall, K.J. et al. J. Bacteriol. (1992) 174:144-154; Fernandez-Moreno, M.A. et al. Cell (1991) 66:769-780; Takano, E. et al. Mol. Microbiol. (1992) 5 6:2797-2804; Gramajo, H.C. et al. Mol. Microbiol. (1993) 7:837-845). The DnrI gene product complements a mutation in the *actII-orf4* gene of *S. coelicolor*, implying that DnrI and ActII-orf4 proteins act on similar targets. A gene (*srmR*) has been described (EP 0 524 832 A2) that is 10 located near the Type I PKS gene cluster for the macrolide polyketide spiramycin. This gene specifically activates the production of the macrolide antibiotic spiramycin, but no other examples have been found of such a gene. Also, no homologues of the ActII-orf4/DnrI/RedD 15 family of activators have been described that act on Type I PKS genes. WO 98/01546 describes the use of the ActII-orf4 family of activators in conjunction with their cognate promoters (e.g *actII-orf4* with the *actI* promoter) in a heterologous actinomycete to obtain high level 20 expression of recombinant Type I polyketide synthase genes.

Although large numbers of therapeutically important polyketides have been identified, there remains a need to obtain novel polyketides that have enhanced properties or 25 possess completely novel bioactivity. The complex

polyketides produced by Type I PKSs are particularly valuable, in that they include compounds with known utility as anthelmintics, insecticides, immunosuppressants, antifungal agents or antibacterial agents. Because of their structural complexity, such novel polyketides are not readily obtainable by total chemical synthesis, nor by chemical modifications of known polyketides.

There is also a need to develop reliable and specific ways of deploying individual genes and portions of genes in practice so that all, or a large fraction, of hybrid PKS genes that are constructed, are viable and produce the desired polyketide product. This includes the development of advantageous host strains for expression of such genes. For example many polyketides are rendered bioactive by the action of further enzymes other than the polyketide synthase, and host strains that contain and are able to express the genes for such enzymes are particularly convenient for the efficient synthesis of the bioactive material. In those cases where the construction of a known or a novel polyketide requires specialised precursors, host strains containing and able to express the genes for key enzymes that enhance the production of such specialised precursors are equally valuable and desirable. There is also a need to develop

rational methods of increasing the expression level of all the genes required for production of a specific polyketide. Clearly also a host cell which is advantageous for the above reasons, and/or because of other favourable characteristics including but not limited to its speed of growth, excellent handling characteristics in fermentation, and ease of transformation with DNA by various techniques, can be made even more favourable by the cloning into that cell of such auxiliary genes for polyketide modification, or gene activation, or post-translational modification, or precursor supply.

The DNA sequences have been disclosed for several Type I PKS gene clusters that govern the production of 16-membered macrolide polyketides, including the tylosin PKS from *Streptomyces fradiae* (application EP 0 791 655 A2), the niddamycin PKS from *Streptomyces caelestis* (Kavakas, S.J. et al. J. Bacteriol. (1997) 179:7515-7522) and the spiramycin PKS from *Streptomyces ambofaciens* (application EP 0791 655 A2). DNA sequences have also been disclosed for Type I PKS gene clusters that govern the production of further complex polyketides, for example rifamycin from *Amiclatopsis mediterranei* (WO 98/07868), and soraphen from *Sorangium cellulosum* (US

5716849), but so far no DNA sequence has been disclosed for one of the most widespread and important classes of complex polyketides, the polyethers.

Polyethers form an important group of complex  
5 polyketide antibiotics (Westley, J.W. in "Antibiotics IV. Biosynthesis" (Corcoran, J.W. Ed.), Springer-Verlag, New York (1981) p. 41-73). They are polyoxygenated carboxylic acids which act as selective ionophores transporting cations across the cell membrane of target cells and  
10 thereby causing depolarisation and cell death. Certain polyethers including monensin, lasalocid and tetronasin are in widespread use in animal husbandry as coccidiostats (principally targetted against *Eimeria* spp.) and as growth promoters. Polyethers have also been  
15 reported to be active *in vitro* and *in vivo* against the malarial parasite *Plasmodium falciparum* (Gumila, C. et al. Antimicrobial Agents and Chemotherapy (1997) 41: 523-529).

Polyethers contain multiple asymmetric centres and  
20 are characterised by the presence of tetrahydrofuran and tetrahydropyran rings, producing a characteristic shape which is non-polar on its outer surface and therefore well adapted for transport of material across bacterial membranes; and provides on its inner surface polar  
25 coordinating ligands for a centrally-bound metal ion. In

addition to tetrahydrofuran and tetrahydropyran rings,  
other groups which are often present include spiroketal,  
dispiroketal, and substituted benzoic acid moieties and  
occasionally other groups for example a tetrionic acid or  
5 a 6-membered carbocyclic ring -

Monensins A and B are produced by the actinomycete  
*Streptomyces cinnamonensis*. Their structures are shown in  
Figure 1. Monensin B differs from monensin A only in the  
presence of a methyl sidechain at C-16 rather than an  
10 ethyl sidechain. Monensin selectively binds and  
transports sodium ions. In addition to its antibacterial  
and antifungal properties monensin has some activity  
against protozoal parasites such as the malarial parasite  
*Plasmodium falciparum*. Although the structures of  
15 polyethers differ significantly from those of other  
complex polyketides such as the polyhydroxylated and  
polyene macrolides, their biosynthesis appears to take  
place by a metabolic pathway which has many common  
elements. Thus experiments using carbon 14-labelled  
20 precursors have shown that monensin A is synthesised from  
five acetate, one butyrate and seven propionate units  
(Day, L.E. et al. Antimicrob. Agents Chemother. (1973)  
4:410-414). Similarly experiments using precursors  
doubly-labelled with carbon-13 and oxygen-18 have shown  
25 that oxygens (O)1, (O)3, (O)4, (O)5, (O)6 and (O)10 of

monensin arise from the carboxylate oxygens of either propionate or acetate, while growth in the presence of oxygen-18 oxygen gas demonstrated that the three remaining ether oxygens (O)7, (O)8 and (O)9 are derived from molecular oxygen (Cane, D.E. et al., J. Am. Chem. Soc. (1981) 103:5962-5965; Cane, D.E. et al. J. Am. Chem. Soc. (1982) 104:7274 - 7281; Ajaz, A.A. and Robinson, J.A. J. Chem. Soc. Chem. Commun. (1983) 12:679-680). These findings have been rationalised by proposing that the biosynthesis of monensin proceeds via an acyclic triene intermediate (1) in which the geometry of all three carbon-carbon double bonds is E (entgegen) rather than Z (zusammen). The triene is then proposed to be subject to epoxidation to a tri-epoxide (2) and then ring opening is proposed to occur with concomitant sequential formation of the five ether rings as shown in Figure 2A. Such a biosynthetic pathway, first mooted by Westley in 1974 (Westley J.W. et al., J. Antibiot. (1974) 27:597-604) accounts for the observed stereochemistry at the multiple asymmetric centres in monensin, (Cane, D.E. et al. J. Am. Chem. Soc. (1982) 104:7274-7281; Sood, G.R. et al. J. Chem. Soc. Chem. Commun. (1984) 21:1421-1424) and analogous schemes can be used to account for the biosynthesis of other known polyethers. such as lasalocid A (Hutchinson C.R. et al., J. Am. Chem. Soc. (1981)

103:5953-5956), tetronasin (ICI 139603) (Demetriadou,  
A.K. et al. J. Chem. Soc. Chem. Commun. (1985) 7:408-410)  
and narasin (Spavold, Z. et al. Tetrahedron Letters  
(1986) 27:3299-3302). The hydroxylation at C-26 and the  
5 introduction of an O-methyl group on oxygen 3-are  
proposed to occur as late steps in the biosynthesis,  
after formation of the polyether structure.

Unfortunately key aspects of the biosynthetic scheme  
shown in Figure 2A have so far eluded experimental  
10 confirmation. No biosynthetic intermediates have been  
isolated from mutants of *S. cinnamonensis* that are  
blocked in early stages of monensin production. 26-  
deoxymonensin A has been isolated from a *S. cinnamonensis*  
mutant partially blocked in monensin production  
15 (Ashworth, D.M. et al. J. Antibiot. (1989) 42:1088-1099)  
and 3-O-demethylmonensins A and B have been recovered as  
minor components from the fermentation broth of a  
monensin-producing strain (Pospisil, S. et al. J.  
Antibiot. (1987) 40:555-557). When fed to cells of *S.*  
20 *cinnamonensis* in radio-labelled form, neither  
26-deoxymonensin A, nor 3-O-demethylmonensin A, nor 3-O-  
demethyl, 26-deoxymonensin A were significantly  
incorporated into monensin A (Ashworth, D.M. et al. J.  
Antibiot. (1989) 42:1088-1099), either because they are  
25 actively excluded or because these modifications in fact

occur earlier in the biosynthetic pathway so that these metabolites are shunt products not readily converted into the final antibiotic by the respective hydroxylase or methyltransferase. Similarly, the putative all (E)-triene precursor (1) has been synthesised and shown not to become incorporated into monensin when fed to growing cells of *S. cinnamomensis* (Holmes, D.S. et al. *Helv. Chim. Acta* (1990) 73:239-259). An alternative pathway has been proposed, as shown in Fig 2B, based on the transition-metal-mediated oxidation of 1,5-dienes (Walba, D.M. and Edwards, P.D. *Tetrahedron Lett.* (1980) 21:3531-3534). The triene intermediate (4) would differ from that of Figure 2A (1) only in that each carbon-carbon double bond would have the (Z)-configuration (Townsend, C.A. and Basak, A. *Tetrahedron* (1991) 47:2591-2602) and not the (E)- configuration.

The genetic basis of secondary metabolite biosynthesis essentially exists in the genes which code for the individual biosynthetic enzymes and in the regulatory elements which control the expression of the biosynthetic genes. The genes encoding biosynthesis of polyketides in actinomycetes have hitherto been found as clusters of adjacent genes, ranging in size from 20 kilobasepairs (kbp) to over 100 kbp. The clusters often contain specific regulatory genes and genes

conferring resistance of the producing strain to its own antibiotic.

In various of its aspects the invention provides the following:-

- 5 (1) a DNA sequence encoding at least one-peptide necessary for the biosynthesis of monensin, preferably comprising one or more of the following genes: *mon BI*, *mon BII*, *mon CI*, *mon CII*, *mon H*, *mon RI*, *mon RII*, *mon T*, *mon AIX* and *mon AX* as depicted in the appended sequence  
10 data or an allele or mutation thereof;
  - (2) a DNA sequence according to the first aspect comprising all of the genes listed therein or an allele or mutation thereof;
  - (3) a DNA sequence according to the first aspect  
15 comprising the complete monensin gene cluster;
  - (4) a DNA sequence coding for one or more of the peptides set out below, said peptide having the amino acid sequence as set out in the appended sequence data or being a variant thereof having the specified activity:
- | 20 | <u>peptide</u> | <u>activity</u>                                  |
|----|----------------|--|
|    | <i>mon CII</i> | epoxyhydrolase/cyclase                           |
|    | <i>mon E</i>   | S-adenosylmethionine-dependent methyltransferase |
|    | <i>mon T</i>   | monensin resistance gene                         |

(5) a recombinant cloning or expression vector comprising a DNA sequence according to any of aspects 1-4;

(6) a transformant host cell which has been transformed to contain a DNA sequence according to any of aspects 1-4 and is capable of expressing a corresponding peptide;

(7) a hybridization probe comprising a polynucleotide which binds specifically to a region of the monensin gene cluster selected from *mon BI*, *mon BII*, *mon CI*, *mon CII*,  
25 *mon H*, *mon RI*, *mon RII*, *mon T*, *mon AIX* and *mon AX*;

(8) use of a probe according to aspect (7) in a method of detecting the presence of a gene cluster which governs the synthesis of a polyether, and optionally isolating a gene cluster detected thereby;

5           (9) Use of a probe comprising a polynucleotide which binds specifically to a gene responsible for levels of activity of the monensin gene cluster, preferably a regulatory gene, resistance gene or thioesterase gene, more preferably the regulatory gene *mon RI*, in a method of  
10       detecting an analogous gene in a gene cluster of another polyketide, preferably a polyether, and optionally manipulating the gene detected thereby to alter the level of expression of said other polyketide;

          (10) a host cell, preferably *Streptomyces*  
15       *cinnamomensis*, containing a heterologous gene under the control of the *mon RI* gene and a monensin promoter;

          (11) use of a portion of the monensin gene cluster having chain terminating activity, preferably comprising at least one of *mon AIX* and *mon AX* or a mutant or allele thereof having chain terminating activity, to effect chain  
20       release of a peptide other than one required for monensin biosynthesis;

          (12) use of a portion of the monensin gene cluster having carbon-carbon double bond isomerase activity,  
25       preferably comprising at least one of *mon BI* and *mon BII*

or a mutant or allele thereof having isomerase activity to provide a desired stereochemical outcome in the synthesis of a polyketide other than monensin;

(13) a polypeptide encoded by a portion of the monensin gene cluster, preferably comprising at least one of *mon BI* and *mon BII* or a mutant or allele thereof, having carbon-carbon double bond isomerase activity;

(14) an epoxidase enzyme encoded by *mon CI* or a derivative or variant thereof having epoxidase activity;

(15) a cyclase enzyme encoded by *mon CII* or a derivative or variant thereof having cyclase activity.

Some embodiments of the invention will now be described by way of example with reference to the accompanying drawings in which:

Fig 1 shows the structure of monensins A and B;  
Fig 2 illustrates proposed biosynthetic pathways;  
Fig 3 illustrates the proposed organization of the monensin polyketide synthase (PKS) enzyme complex; and  
Fig 4 illustrates the proposed organization of the monensin biosynthetic gene cluster.

The overall gene organization of the monensin biosynthetic gene cluster, as shown in Fig 4, is similar to that previously found for many macrolide biosynthetic gene clusters, which have one or more open reading frames (ORFs) encoding large multifunctional PKSs flanked by

other genes which encode functions required for the biosynthesis of the antibiotic. In the case of monensin, there is an unusually high number of distinct ORFs encoding PKS multi-enzymes (eight in total, labelled *monAI* to *monAVIII*) but there is again a separate module of enzymes for each cycle of polyketide chain extension, exactly as found for modular PKSs for macrolide biosynthesis (see Fig 3). Thus there are 12 condensations predicted to be required for the production of the carbon skeleton of monensin, and in agreement with this there are found to be 12 extension modules of PKS enzymes distributed among the 8 PKS ORFs. However, as mentioned in detail below, the other genes in the monensin cluster include genes which have not previously been found in any other gene cluster for the biosynthesis of a complex polyketide, and which are not significantly similar to any genes in published sequence databases. The cloned DNA for these genes is useful to allow the diagnosis that a polyketide biosynthetic gene cluster in any actinomycete, uncovered previously by conventional hybridization against a PKS gene probe from (say) the DEBS or some other characterised PKS gene cluster, is one that governs the synthesis of a polyether; and these genes are also valuable either singly or in combination as specific hybridization probes for the specific detection and

isolation of additional polyether biosynthetic gene clusters. Examples of these previously-unknown genes are the genes *monBI*, *monBII*, *monCI* and *monCII*. In addition the regulatory genes *monH*, *monRI*, and *monRII* and the resistance gene *monT* and the thioesterase genes *monAIX* and *monAX* are all useful for the detection of analogous genes in other polyether clusters which are required for the rational manipulation of such genes in order to increase levels of the specific product.

The cloned and sequenced cluster of genes for monensin biosynthesis is useful secondly in the engineering of mutant strains of *S. cinnamonensis* and of other actinomycetes which are suitable strains for the high level production of either natural or novel recombinant polyketides. The sequence of the monensin cluster disclosed here shows the surprising fact, that the gene cluster contains a gene *monRI* whose gene product has an amino acid sequence highly similar to that of *actII-orf4*, the pathway-specific activator gene which activates the *actI* and other promoters of the actinorhodin biosynthetic gene cluster of *Streptomyces coelicolor*. The recognition of this aspect of the natural regulation of a Type I PKS cluster is important and valuable because first, it is possible to increase the yield of monensin by increasing the level of the activator MonRI, either by

placing the gene *monRI* under the control of a powerful promoter or arranging for the presence within the cells of one or more additional copies of the *monRI* gene (as exemplified below); secondly, it will be possible to use the *monRI* gene as a specific hybridisation probe to locate similar genes in other complex PKS gene clusters, especially other polyether PKS gene clusters but also polyene and macrolide gene clusters and all other Type I modular PKS gene clusters; even in cases where (as for rapamycin and erythromycin) no such gene has been previously found within the currently accepted physical limits of the relevant biosynthetic gene cluster. In such cases the *monRI* gene probe might be expected to uncover the activator even if it resides on the chromosome at some distance from the main body of the gene cluster; and simple experiments would then show whether the activator(s) so uncovered are involved in regulation of the biosynthesis of those particular metabolites; thirdly, increasing the copy number of the *monRI* gene or of any of the activator genes uncovered will tend to increase the yield of a heterologous polyketide by "crosstalk" where the activator mimics the presence of the normal activator for the transcription of the genes for that heterologous polyketide synthase. It is clear from recently published work (Wietzorrek, A. and Bibb, M. Mol. Microbiol. (1997)

25:1181-1184) that the ActII-orf4 family of activators exert their effects by binding to promoter regions within the target gene cluster, so it will be possible to use the *monRI* gene together with monensin promoter regions to drive the high-level transcription and translation of heterologous genes in *Streptomyces cinnamonensis*, and perhaps in other host strains too; such genes need not be PKS genes or even involved in polyketide biosynthesis. Monensin promoter regions are found at the 5' end of genes or groups of genes in the cluster and their location is clear from the sequence analysis disclosed here. Thus a useful vector would provide the monensin promoter and the ribosome binding site and continue up to the start of the open reading frame, after which the monensin ORF naturally found there would be replaced by the heterologous gene. The relative strength of the monensin promoters can be readily determined using any one of a number of known promoter probes, i.e. genes whose expression gives rise to readily measurable and quantifiable effects, such as Green Fluorescent Protein (GFP); or beta-galactosidase in the presence of a chromogenic substrate. It should be possible to mutate randomly the small region of the monensin promoters especially likely to interact with the MonRI activator (identified by the presence of tandem heptanucleotide repeats with a common consensus sequence

between the various monensin promoters) (Wietzorrek, A. and Bibb, M. Mol. Microbiol. (1997) 25:1181-1184), and to determine the optimal DNA sequence for the maximal activation effect using either *S. cinnamonensis* (preferably - in case there are other unknown factors that make the activation function better in this strain than in other heterologous systems), or even in another host actinomycete strain. If the natural monensin promoters were mutated to have this optimal recognition sequence, then this would further increase the production of monensin. By extension, the use of this modified monensin promoter in conjunction with the *monRI* gene in heterologous systems could form the basis of further improvements in expression of polyketide synthases or other genes, either by appropriate chromosomal alterations to introduce the altered promoter and also the *monRI* gene; or by provision of vectors containing these optimised signals linked to specific genes and housed in suitable host cells.

The sequencing of the monensin cluster has uncovered another strategy for gene regulation in such Type I clusters. The previously-sequenced genes for the rapamycin biosynthetic pathway in *Streptomyces hygroscopicus* included a gene of unknown function (*rapH*). A closely similar gene has now been found in the monensin

biosynthetic gene cluster (*monH*), and it is clear from this recurrence (and the comparison of the sequences with those of database proteins) that this gene is potentially an important DNA-binding sensor gene which acts to  
5 regulate the transcription of the cluster in concert with other regulatory signals. Simple experimentation is needed in order to define whether the gene is an activator, in which case putting in another copy or increasing its transcription will have the potential to increase  
10 polyketide biosynthesis; or alternatively the *rapH* gene product may be a negative regulator, whereupon deletion of this gene may release the biosynthetic pathway from this inhibitory effect and increase yields.

There is a continuing need to develop new methods of  
15 high-level production of bioactive metabolites and other valuable gene products in actinomycetes. *Streptomyces cinnamonensis* is a recognised and very valuable industrial strain for the production of very high levels of monensin, it is readily transformable with DNA by standard methods  
20 of conjugation or of protoplast transformation, it is a host for numerous known broad range plasmids including well-known expression plasmids of both high- and low-copy number, it also grows quickly relative to other actinomycete strains (for example about three times faster  
25 than wild type *Saccharopolyspora erythraea* the

erythromycin producer, under comparable conditions) and sporulates relatively easily. Heterologous polyketides can be expressed in *Streptomyces cinnamonensis* using for example the low-copy number plasmid pCJR24 (which has no origin of replication active in actinomycetes so is maintained by integration into the chromosome) (Rowe, C. et al. Gene (1998) 216:215-223) or the related plasmid pCJR29 in which the polyketide synthase gene(s) are placed under the control of the *actI* promoter which is activated by the ActII-orf4 activator; or alternatively the *monAI* promoter can be substituted together with the MonRI activator; or some other pairing of activator and cognate promoter chosen from either a Type II or a Type I polyketide synthase gene cluster. As an example, the wild type strain of *Streptomyces cinnamonensis* has been used to express the plasmid pCJR29 (Rowe, C. et al. Gene (1998) 216:215-223) containing as insert the three ORFs for the PKS governing the production of 6-deoxyerythronolide B, the macrolide precursor of erythromycin A in *Saccharopolyspora erythraea*, these genes being placed under the control of the pathway-specific *actI* promoter from *Streptomyces coelicolor* together with its cognate activator gene *actII-orf4*. The transformed strain when cultivated in a suitable liquid medium produced 6-deoxyerythronolide B in good yield.

It is well known to the person skilled in the art that it is possible to use standard vectors unable to replicate in actinomycetes to introduce DNA into a *Streptomyces* cell, such DNA comprising two portions of contiguous DNA which are each identical to one of two portions of the cell's chromosome that are spaced up to 100 kbp apart; and that through recombination between the incoming DNA and the chromosome occurring in both portions of DNA the net result is that the chromosomal sequence is replaced by the defective sequence originally that of the incoming DNA. Such a procedure has been applied to the monensin-producing strain of *S. cinnamonensis* as described in detail below, and a strain of *S. cinnamonensis* has been obtained that carries a specific deletion in the monensin cluster and which is unable to produce the antibiotic. The use of such a strain facilitates the production of heterologous polyketides by removal of the background of monensin production.

The multiple uses of portions of the cloned and sequenced DNA from the monensin cluster will readily occur to the person skilled in the art. A surprising feature of the PKS of the monensin cluster is an unusual mechanism of polyketide chain initiation. We have found that the monensin PKS loading module has three domains, which from the amino-terminus of the protein are: a KSq domain, an

acyltransferase domain and an ACP domain. We have uncovered this organisation in the PKS for the 14-membered macrolide oleandomycin as well as in the monensin PKS, an organisation of the loading module previously only found  
5 for the 16-membered macrolides and in which the KSq domain (which looks like a ketosynthase or condensation domain except that the active site cysteine residue is substituted by a glutamine for which the single letter notation is Q) had been previously speculated to have no  
10 function. It was realised that the acyltransferase of the loading module actually has malonyl-CoA and not acetyl-CoA as a substrate and that KSq is an active decarboxylase. It appears that a better discrimination can be achieved in the selection of the smaller acetate unit over propionate  
15 if the choice is made initially between methylmalonyl- and malonyl-CoA.

An unprecedented feature of the monensin PKS genes is that no integral chain-terminating domain is present as a C-terminal appendage of the PKS extension module that  
20 catalyzes the twelfth and final chain extension. Because the product of the monensin PKS is a carboxylic acid, it would have been firmly predicted that chain release would have been catalyzed by such a C-terminal domain containing a "thioesterase" activity. Previously sequenced PKS gene  
25 sets have been of two sorts: first, those macrolide PKSs

typified by erythromycin, spiramycin, tylosin, niddamycin  
which have a readily recognisable C-terminal  
"thioesterase" domain, which in these enzymes functions as  
a specific cyclase rather than releasing the polyketide  
5 product as a free carboxylic acid; secondly, those  
macrolide PKSs typified by rapamycin, FK506, and  
rifamycin, where there is an alternative and recognised  
mode of chain termination by transfer of the polyketide  
chain to an acceptor moiety, catalyzed by a specific  
10 enzyme (eg pipecolate incorporating enzyme for rapamycin  
(Schwecke T. *et al.* Proc. Natl. Acad. Sci. USA (1995)  
92:7839-7843) and FK506 (Mothamedi H. and Shafiee A, Eur.  
J. Biochemistry (1998) 256:528-534); arylamine synthetase  
for rifamycin (August P.R. *et al.* Chemistry & Biology  
15 (1998) 5:69-79).

The monensin PKS surprisingly falls into neither  
category, and therefore seems to be the first example of a  
novel mode of chain termination. It is novel and  
noteworthy in this connection that the monensin PKS gene  
20 cluster contains two small genes that encode discrete,  
monofunctional thioesterase enzymes. Although many PKS  
gene clusters have been previously shown to contain one  
such discrete thioesterase, none have been shown to have  
two. The role of such thioesterases is not known, although  
25 in the case of methymycin/pikromycin PKS, which has been

reported to be responsible for the biosynthesis of both  
the 12-membered macrolide methymycin and the 14-membered  
macrolide pikromycin (Xue Y.Q. Proc. Natl. Acad. Sci. USA  
(1998) 95:12111-12116) the disruption of this thioesterase  
5 reportedly caused a ten-fold drop in the amount of both  
macrolides produced. A similar finding has been reported  
for the discrete thioesterase of the tylosin PKS gene  
cluster (Cundliffe E. et al. Chemistry & Biology in  
press). Additional copies of such thioesterases may  
10 therefore accelerate the production of specific  
polyketide, but this has not yet been demonstrated.  
However, the presence of the discrete thioesterase is not  
completely essential for polyketide production.

It is highly desirable to have a broadly effective  
15 method of catalysing the release of polyketide gene  
products from a PKS as the free acid. The well-studied  
integral thioesterase domain in the erythromycin PKS  
thioesterase has a broad specificity in cyclization to  
form a lactone (assuming that a hydroxy group is present  
20 in the growing polyketide chain at an appropriate  
position), but hydrolysis to form the free acid is very  
slow. The recognition of the unusual arrangement of the  
monensin PKS means that it is now possible to harness  
either the entire PKS module that catalyses the twelfth  
25 and final extension cycle in monensin biosynthesis, or the

C-terminal portion of it, and graft it onto a different polyketide synthase by genetic engineering, so as to allow the release mechanism characteristic of monensin to operate in a different context. The use of this portion  
5 only of the monensin PKS suffices to allow the novel mechanism of chain release to operate successfully. The speed of the polyketide chain hydrolysis in a given case can depend on the additional presence of one or both of the discrete thioesterase genes (*monAIX* and *monAX*) from  
10 the monensin gene cluster. The use of this novel method of chain termination represents a valuable way of generating a large number of novel engineered polyketides that are currently inaccessible, and ensuring that the products have a specified chain length.

15       The genes *monBI* and *monBII* appear to encode very similar enzymes with significant amino acid sequence similarity to authentic ketosteroid isomerases which are known to catalyse the migration of an activated carbon-carbon double bond. The conservation of active site  
20 residues makes it very likely that these *mon* genes govern a reaction involving activated double bonds in the biosynthetic pathway to monensin and this surprising observation can be accommodated if the initial product of the polyketide chain growth on the monensin PKS is a  
25 linear precursor in which the double bonds were initially

formed with a conventional *trans* or *E* (*entgegen*) geometry; but before the polyketide chain was extended by insertion of the next unit the *monBI* and/or the *monBII* gene product(s) catalyse the specific rearrangement of the newly-created double bond into the *cis* or *Z* (*zusammen*) geometry. This new view of the monensin biosynthetic pathway allows the deduction that the *monBI* and *monBII* genes, perhaps in combination with specific portions of the monensin modules where they normally exert their effects (namely modules 3, 5 and 7) might be used in order to achieve the extremely desirable targetted biosynthesis of novel polyketides containing double bonds with *Z* geometry at specified point(s) along the chain. Thus for example it should be possible to provide for the direct biosynthesis of C22-C23 *cis* or *Z* double bond in avermectins, thus avoiding tedious and expensive chemical conversion of an initial fermentation product into this important anthelmintic. Only limited experimentation is needed to see whether the *monBI* and/or *monBII* gene products are sufficient or whether the *mon* PKS at modules 3, 5 and 7 forms part of the specific docking site(s) for the isomerases and therefore must also be used in the creation of the hybrid PKS that will insert the *cis* or *Z* double bond at the desired position. The substrate specificity of the isomerases need not be limited to 2,3-

unsaturated thioesters. The purified enzymes could also be used to effect such isomerisations *in vitro*, depending on the position of the equilibrium or whether further enzymes are used to achieve the further transformation of the product as it is formed (*vide infra*).

The product of the *monCI* gene is a novel oxidative enzyme with some sequence similarity to authentic examples of such enzymes in the databases; and with a clearly definable role in the monensin biosynthetic pathway, the epoxidation of the double bonds at three separate positions in the initially-formed acyclic intermediate in monensin biosynthesis. This epoxidase could therefore be used in conjunction with *monBI/monBII* gene products to effect oxidative reactions on suitable substrates *in vitro* and *in vivo*. Similarly the *monCII* gene product is a putative cyclase that opens the epoxides and causes the formation of ether rings in monensin.

Any or all of the *monBI*, *monBII*, *monCI* or *monCII* genes may be introduced into a heterologous strain containing the gene cluster for another polyether, in order to divert the biosynthetic pathway and produce a polyketide of altered structure. In these experiments the analogues of these *monB* genes could either be present or (once located and characterised using the *mon* genes as probes) they may be deleted prior to the introduction of

the *monB* and *monC* genes into that strain. The converse experiment in which analogues of the *monB* and *monC* genes from other strains are introduced into *S. cinamomensis* likewise has the potential to produce novel oxidised polyketides. Also, the *monB* and *monC* genes or their analogues may be introduced into a strain that normally produces a macrolide or a polyene or some other complex polyketide and expressed there, when they may effect the diversion of the growing polyketide chain on a heterologous modular PKS towards a new product, which may or may not have the structure of a polyether.

The availability of the monensin gene sequence allows the institution of domain swaps to alter the acyltransferase (AT) specificity of a given module, for example the ethylmalonyl-CoA specific extender found in one of the modules of the monensin PKS can be used to replace one of the other ATs to generate an ethyl side branch at that position in the chain, or the AT can be used to substitute in any other (e.g. macrolide) PKS, as described in WO 98/01571 and WO 98/01546. Similarly the alteration of the level of reduction in a module, by manipulation of the reductive enzymes, can be applied to the monensin genes and here it will produce, depending on which module is affected, either an altered monensin, or a

species which is only partly cyclised, or a polyether with an altered pattern of cyclisation, or even a linear polyketide.

5 In general the targetted alteration of the pattern of substitution of sidechains or reduction level along the polyketide chain produced by the monensin PKS will, like the disruption or deletion of the oxidative enzymes mentioned above, lead to non-polyether polyketide products. It should be possible, by introduction of the  
10 DEBS thioesterase at the C-terminus of one of the later modules of the monensin PKS, together with an appropriately placed hydroxy group earlier in the chain, to produce novel macrolide products from this polyether PKS system, or alternatively novel polyenes of defined  
15 chain length and chosen ring size.

Example 1Cloning of the monensin A biosynthetic gene cluster using  
DNA probes derived from the erythromycin-producing  
polyketide synthase of *Saccharopolyspora erythraea*

5           A genomic library of the monensin A producing strain  
*Streptomyces cinnamomensis* ATCC 15413 was constructed  
using methods well-known in the art, namely, the  
production of high molecular weight genomic DNA, followed  
by the partial cleavage of this DNA using the frequent-  
10       cutting restriction enzyme *Sau3A*, fractionation of the  
fragments on a sucrose gradient and selection of fragments  
of average size 35-40 kbp, and the cloning of these  
fragments into the cosmid vector pWE15 (Evans, G.A. et al.  
Gene (1989) 79:9-20) which had been previously digested  
15       with *Bam*HI and treated with shrimp alkaline phosphatase.  
The library was packaged and transfected into *Escherichia*  
*coli* XL-1 Blue MR cells. The library was plated out on  
2xTY agar medium (10 g tryptone, 10 g yeast extract, 5 g  
NaCl, 15 g bactoagar per litre containing ampicillin 50  
20       μg/ml) for cosmid selection and the colonies were allowed  
to grow overnight. The library was then screened by  
hybridisation using as a probe DNA encoding the  
ketosynthase domain of module 1 of the erythromycin-  
producing PKS (6-deoxyerythronolide B synthase, DEBS) of  
25       *Saccharopolyspora erythraea*. The colonies giving a

positive hybridisation signal in the hybridisation were selected and the cosmid DNA from each colony was purified and mapped by restriction digestion. The presence of the target biosynthetic genes on a cosmid was verified by sequencing of the ends of the cosmid inserts using the commercially available T3 and T7 primers which hybridise specifically to the respective ends of each cosmid insert (Evans, G.A. et al. Gene (1989) 79:9-20).

#### Example 2

#### 10 Sequencing of the biosynthetic gene cluster for monensin A from *Streptomyces cinnamonensis*

Three cosmids obtained by screening of the genomic library of *S. cinnamonensis* were used to obtain the entire DNA sequence of the monensin biosynthetic gene cluster. These cosmids, MO.CN02, MO.CN11 and MO.CN33 between them contain the entire DNA sequence of the cluster and the adjacent regions of the chromosome. They have been deposited in NCIMB, 23 St Machair Drive, Aberdeen AB24 3RY, UK, under the NCIMB accession numbers 40956 (MO-CN11); 40957 (MO-CN33) and 40958 (MO-CN02) respectively.

The DNA of each cosmid was separately subjected to partial digestion with *Sau3A* and fragments of approximately 1.5-2.0 kbp were separated by agarose gel electrophoresis. The fragments were then ligated into the

plasmid vector pUC18 (Messing, 1982), previously digested with *Bam*HI and treated with shrimp alkaline phosphatase. The library was transformed into *E. coli* strain XL1-Blue MR and plated on 2xTY agar medium containing ampicillin  
5 (100 µg/ml) to select for plasmid-containing cells. Plasmid DNA was purified from individual colonies and sequenced using the Sanger dye-terminator procedure on an ABI 377 automated sequencer (Sanger, F. Science (1981) 214:1205-1210). The sequence data obtained from single  
10 random subclones of a cosmid was assembled into a single continuous sequence and edited using GAP4.1 program of the STADEN gene analysis package (Staden, R. Molecular Biotechnology (1996) 5:233-241).

The sequence is set out in the appended sequence  
15 listing.

Tables I and II contain data about individual genes and gene products.

### Example 3

#### Inactivation of the monensin A biosynthetic gene cluster

20 A chromosomal gene disruption experiment was used to verify the identity of the cloned polyketide synthase gene cluster. Plasmid pMOB6314 is a pUC18 sequencing subclone of the presumed monensin A biosynthetic gene cluster prepared as described in Example 1, whose inserted DNA  
25 comprises the DNA sequence from nucleotide 9763 to

nucleotide 10108 in SEQ ID 1, and which therefore contains a region of DNA wholly internal to *orfE*, a putative 3-O-methyltransferase. A *Hind*III fragment containing the thiostrepton resistance gene *tsr* from plasmid pIJ702  
5 (Katz, E. et al. J. Gen. Microbiol. (1983) 129:2703-2714) was cloned into the *Hind*III site of plasmid pMOB6314 and the ligation mixture was used to transform *E. coli* cells. Transformants bearing the required plasmid pMOΔE01 were identified by isolation of plasmid DNA and analysis by  
10 restriction digestion. pMOΔE01. Plasmid pMOΔE01 was used to transform protoplasts of *Streptomyces cinnamonensis* as described by (Hopwood D.A. et al. (1985)). Since plasmid pMOΔE01 lacks an origin of replication that is active in *Streptomyces*, growth in the presence of thiostrepton (25  
15 µg/ml) in the regeneration medium led to the isolation of stable integrants. Isolated putative integrants were tested for the presence of integrated pMOΔE01 sequences by Southern hybridisation. A clone of *Streptomyces cinnamonensis* identified by its restriction pattern in  
20 Southern hybridisation as bearing pMOΔE01 integrated in the region of *monE* of the monensin A biosynthetic gene cluster was designated *S. cinnamonensis* MO-DD01.

Detection of production of the monensin A related metabolites produced by *S. cinnamonensis* MO-DD01 was  
25 performed by GC-MS analysis of methanol extracts of the

entire broth harvested in 72 hours of growth of the strain. No significant amounts of monensin A-related metabolite production were detectable.

Example 4

5     Overproduction of erythromycin aglycone in *Streptomyces cinnammonensis*

*S. cinnammonensis* is a suitable system for overproduction not just of monensin A but also of other polyketide metabolites. Established techniques of genetic transformation allow fast introduction of foreign polyketide producing genes sets into this host. Fast growth of *S. cinnammonensis* in liquid culture and optimal precursor supply favour high yield of polyketide metabolites.

15           Construction of pIB061

*S. erythraea* NRRL2338 was transformed with pCJR30 (Rowe, C. J., et al. (1998) Gene 216:215-223) using a routine protoplast transformation technique as described by Hopwood et al. (1985). A stable integrant of *S.*  
20     *erythraea* [pCJR30] was identified and the production of 10mg/L of the triketide lactone (delta lactone of (2S,3R,4R,5R)-2,4-dimethyl-3,5-dihydroxy-heptanoic acid) in addition to erythromycins was confirmed by MS analysis.

25           Total DNA of *S. erythraea* [pCJR30] was purified and

approximately 200 ng was digested with *EcoRI* endonuclease. The digestion mixture was precipitated with isopropanol and the resulting DNA was treated with T4 DNA-ligase for 16 hours at 16°C. The ligation mixture was used to transform *E.coli* DH10B cells. The transformants were screened for the presence of the plasmid. A clone containing a 44.7kb plasmid was identified and confirmed by restriction analysis to contain three complete genes: *eryAI*, *eryAII* and *eryAIII*. The plasmid was named pIB061.

#### Transformation of *S. cinnamonensis*

Protoplasts of *S. cinnamonensis* were prepared by a modified procedure of Hopwood et al. (1985). Plasmid pIB061 was transformed into the protoplasts of *S. cinnamonensis* and stable thiostrepton resistant colonies were isolated. Individual colonies were checked for their plasmid content and the presence of plasmid pIB061 was confirmed by its restriction pattern. *S. cinnamonensis* (pIB061) was inoculated into 250 ml of M-C3 minimal production medium containing 10 µg/ml of thiostrepton and allowed to grow for 72 hours at 30 °C. After this time the mycelia were removed by filtering. The broth was extracted with two volumes of ethyl acetate and the combined ethyl acetate extracts were washed with an equal volume of saturated sodium chloride, dried over anhydrous sodium sulphate, and the ethyl acetate was removed under reduced

pressure to give about 200 mg of crude product. The product was analysed by LCQ and mass was confirmed to that of erythronolide B.

This example demonstrates the importance of *S. cinna-*  
5 *monensis* for production of high levels of foreign polyketide antibiotics. Introduction of the complete erythromycin gene cluster or other gene clusters into this system are likely to produce high levels of the corresponding metabolites.

10 Example 5

Construction of plasmid pCJW58 containing the monensin  
activator gene under the ermE\* promoter

The ermE\* promoter derived from the ermE resistance methyltransferase gene of *S. erythraea* (Bibb et al. Gene  
15 (1985) 38:215-226) was amplified by PCR as a SpeI-XbaI fragment using the following oligonucleotides  
5'-CCACTAGTATGCATGCGAGTGTCGTTTCGAGT-3' and 5'-  
TTGTATACACCTAGGATGGTTGGCCGTGC-3' with pRH3 (Dhillon et al. Molecular Microbiology (1989) 3:1405-1414 as a template  
20 and cloned into SmaI-digested, phosphatase-treated pUC18, to produce plasmid pIB135. The integrative plasmid pSET152 (Bierman, M. et al. (1992) Gene 116:43-49)) was digested with XbaI and the backbone was dephosphorylated and  
ligated to the SpeI-XbaI fragment of pIB135 containing the  
25 ermE\* promoter. The ligation mixture was used to

transform *E. coli* DH10B and the orientation of the insert in the plasmids from individual clones was checked by using restriction analysis. A plasmid with the *ermE*\* promoter oriented so that the *NdeI* and *XbaI* sites are  
5 adjacent to the apramycin resistance gene was selected and named pIB139.

The *monR* gene from the monensin biosynthetic gene cluster was amplified and *NdeI* and *XbaI* restriction sites introduced at 5' and 3' ends respectively, by PCR using as  
10 primers the following oligonucleotides:

5'-AGA TAC CAT ATG CTG GGC CCG CTC CGC AT -3'

and 5'-AAT GCT CTA GAC TGT CAG CGA CCG GAC AGG GCC AA-3'

and cosmid MO.CN11 as template. The PCR product was ligated into *SmaI*-treated and phosphatase-treated plasmid  
15 pUC18 and the ligation mixture was used to transform *E. coli* DH10B cells. Transformant colonies were analysed for the presence of plasmid and the identity of the plasmid inserts was verified by sequencing. A plasmid whose insert contained the *monR* gene flanked by *NdeI* and *XbaI*  
20 restriction sites was selected and designated pCJW57.

Plasmid pCJW57 was digested with *NdeI* and *XbaI* and the fragment containing the *monR* gene was ligated together with the backbone of plasmid pIB139 which had been digested with the same two restriction enzymes, and  
25 purified by gel elution. The ligation mixture was used to

transform *E. coli* strain DH10B cells. Transformant colonies were analysed for the presence of plasmid and the identity of the plasmid inserts was verified by restriction analysis. One such recombinant was selected  
5 and named plasmid pCJW58.

Plasmid pCJW58 was used to transform the methylation-deficient *E. coli* strain ET 12567 (MacNeil D. J. et al. (1992) Gene 111:61-68) and the recovered, unmethylated plasmid was then used to transform the same *E. coli* strain  
10 ET12567 housing the plasmid pUB307, a derivative of RP4 which is *mob*<sup>-</sup> and which contains a gene for kanamycin resistance (Piffaretti, J. C. et al. (1988) Mol. Gen. Genet. 212:215-218). Recombinants were plated on 2 x TY agar medium containing apramycin and kanamycin at final  
15 concentrations of 50 micrograms per ml and 50 micrograms per ml respectively. The plasmid content of recombinants was checked isolation of plasmid DNA and checking of the identity of these plasmids by restriction analysis. One such clone which contained both pUB307 and plasmid pCJW58  
20 was selected and used for further experiments.

Construction of *Streptomyces cinnamonensis* (pCJW58) and production of monensins

A single colony of *E. coli* ET12567 housing both pUB307 and pCJW58 was toothpicked into 3 ml of TY liquid  
25 medium, containing apramycin and kanamycin at 25 and 25

micrograms respectively, and grown overnight at 37°C. This culture was used to inoculate 25 ml of TY medium, supplemented with the same antibiotics at the same concentrations, and growth was continued until the  
5 absorbance at 600 nm (1 cm pathlength) was between 0.3-0.6. The cells were centrifuged (room temperature, 7 minutes, 2000 x g), resuspended in TY liquid medium (10 ml) containing no added antibiotics, re-centrifuged as before, then resuspended in 2ml of TSB medium and placed  
10 on ice. Meanwhile, 0.5 ml of TSB medium was added to 100 microL containing approximately 10<sup>8</sup> spores of *S. cinnamonensis*. After a brief heat shock, at 50°C for 10 minutes, the suspension was briefly cooled, mixed with 0.5 ml of donor *E. coli* cells, and plated on solid A  
15 medium, which has composition as follows:

A medium

	Sigma wheat starch	5g
	Corn steep powder	1.25g
20	Yeast extract	1.5g
	CaCO <sub>3</sub>	1.5g
	FeSO <sub>4</sub>	6 mg
	DIFCO agar	10g
	H <sub>2</sub> O	to 500 ml
25	pH adjusted to pH 7 with KOH.	

And to which in addition was added 10 mM  $\text{MgCl}_2$  to a final concentration of 10 mM.

The plates were allowed to dry overnight at room  
5 temperature, and were then allowed to incubate a further  
18 hours at 30°C. After this time each 25 ml plate was  
overlaid with a solution of apramycin (final concentration  
50 micrograms per ml) and nalidixic acid (final  
concentration 20 micrograms per ml), and the plates were  
10 allowed to incubate for four days at 30°C. At this time  
individual colonies were toothpicked onto solid A medium  
and allowed to grow. Four representative colonies from  
the A medium plate were grown up in liquid modified YEME  
medium, which has composition as follows:

15 Modified YEME medium

Sucrose	100g
DIFCO Yeast extract	3g
Bacto peptone	5g
Oxoid Malt extract	3g
20 Glucose	10g
H <sub>2</sub> O to 1L	
pH adjusted to pH 7.2 with NaOH.	

These cultures were used to provide a 2% vol/vol  
inoculum for 30 ml of modified YEME which was grown for 7  
25 days, and then transferred to SM16 medium, which has

composition as follows:

SM16 medium

	3-[N-Morpholino]-propane sulfonic acid	
5	(MOPS) buffer	20.9g
	L-proline	10.0g
	Glucose	20g
	NaCl	0.5g
	K <sub>2</sub> HPO <sub>4</sub>	2.1g
10	Ethylenediaminetetraacetic acid, sodium salt	0.25g
	MgSO <sub>4</sub> .7H <sub>2</sub> O	0.49g
	CaCl <sub>2</sub> .2H <sub>2</sub> O	0.029g
	Trace elements solution (Hopwood, D. A. et al. (1985) Genetic Manipulation of <i>Streptomyces</i> - a Laboratory Manual, at p.235)	2 ml
15	0.5 M CoCl <sub>2</sub> solution	2 microlitres
	H <sub>2</sub> O to 1L	
20	pH adjusted to pH 7 with NaOH.	

After growth for a further 7 days, mycelium was collected by centrifugation at 2000 x g for 30 minutes, and the supernatant was extracted three times with 300 ml of ethyl acetate. The combined extracts were concentrated by evaporation under reduced pressure to an oil, which was

mixed with 1 ml of methanol. Samples were applied to an  
 LCQ liquid chromatograph fitted with a mass spectrometer  
 detector unit. The column used was a C18 reversed phase  
 column, equilibrated with a mixture of 80% 20mM ammonium  
 5 acetate/20% acetonitrile, and the column was eluted with a  
 gradient of increasing acetonitrile, reaching 100%  
 acetonitrile over 24 minutes. Monensins A and B emerged  
 from the column with retention times respectively of 8.2  
 minutes and 9.2 minutes. The relative amounts of monensin  
 10 produced by three independent clones (A-C) containing an  
 additional copy of the *monR* gene were compared to a  
 control fermentation of the wild type *S. cinnamonensis*  
 strain, with the results shown in the Table below:

15 Table showing increased monensin production in strains  
bearing additional copy of *monR* gene

Strain	monensin A	monensin B
	concentration	concentration
	(arbitrary units)	(arbitrary units)
Control	188	861
20 A	430	1 800
B	450	1 300
C	249	1 300

#### Example 6

#### Construction of *S. cinnamonensis* M12AT5

25 A region lying immediately 5' of the DNA encoding the

acyltransferase (AT12) domain of module 12 of the monensin polyketide synthase in the monensin biosynthetic gene cluster was amplified with the following primers: 5'-GGTGGCCACGGAAACACCAACACCGGACCCGCGCC-3', and 5'-CTCTCGGAGGCCCGGCGCAACGGCCACAA-3', 3' using cosmid MO-CN11 as a template. The PCR product was ligated into *Sma*I digested and phosphatase-treated plasmid pUC18 and the ligation mixture was used to transform *E. coli* DH10B cells. Transformant colonies were analysed for the presence of plasmid and the identity of the plasmid inserts was verified by sequencing. A plasmid whose insert contained a fragment upstream of the AT12-encoding sequence from about 82.3kb to 83.2kb of the mon cluster was designated pMO81. Similarly a region lying immediately 3' of the DNA encoding the acyltransferase (AT12) domain of module 12 of the monensin polyketide synthase in the monensin biosynthetic gene cluster was amplified with the following primers: 5'-GGCCTAGGGCTGCCTCGGGTGGTGGATCTGCCGA-3' and 5'-TGGTCGGGCGCGGTGCGTGCGATACGT-3', using cosmid MO-CN11 as a template. The PCR product was ligated into *Sma*I-treated and dephosphorylated pUC18 and the ligation mixture was used to transform DH10B *E. coli* cells. Transformant colonies were analysed for the presence of plasmid and the identity of the plasmid inserts was verified by sequencing. A plasmid whose insert contained

a fragment downstream of the AT12-encoding sequence, from 80.5kb to 81.4kb of the *mon* cluster, was designated pMO82.

The DNA encoding AT of module 5 was amplified and *MscI* and *AvrII* restriction enzyme recognition sites were introduced at the ends by PCR using the following primers:  
5'-CCTGGCCAGGGCGGCCAGTGGGTGGGCATG-3' and 5'-  
GGCCTAGGGGTCGGCCGGAACCAGCGCCGCCAGT-3' and the cosmid MO-  
CN33 as a template. The PCR product was ligated into *SmaI*-  
treated and dephosphorylated pUC18 and the ligation  
mixture was used to transform DH10B *E.coli* cells.  
Transformant colonies were analysed for the presence of  
plasmid and the identity of the plasmid inserts was  
verified by sequencing. A plasmid whose insert DNA, with  
sequence from about 44.2kb to 45.2kb of the *mon* cluster,  
encoded the AT5 domain was designated pMO83.

pMO81 was digested with *MscI* and *HindIII* and ligated  
to the 0.9kb *MscI* - *HindIII* fragment of pMO82. A clone  
containing both fragments was designated pMO84. Plasmid  
pMO84 was cleaved with *AvrII* and *HindIII*, treated with  
phosphatase, and ligated together with the 1.0 kb *AvrII* -  
*HindIII* fragment of pMO83 to produce pMO85, which contains  
the DNA encoding the AT5 domain flanked by DNA from either  
side of the DNA encoding the AT12 domain of the monensin  
PKS. The thiostrepton resistance gene *tsr*, derived from  
plasmid pIJ702 (Katz, E. et al., J. Gen. Microbiol.

1983), was cloned into the *HindIII* site of pM085. The resulting plasmid pM086 was analysed by its restriction pattern and confirmed to contain all the desired elements.

5           Plasmid pM086 was used to transform *S. cinamonensis* protoplasts as described by Hopwood, D. A. (1985). Stable thiostrepton-resistant transformants were isolated and checked for the desired integration of the pM085 into the AT12 flanking regions by Southern blot hybridisation. One  
10 such integrant, *S. cinamonensis* M0-08, containing pM085 integrated upstream of the AT12, was passed through 4 cycles of sporulation on a non-selective nutrient medium. Spores obtained after the fourth cycle were replica-plated onto media with and without thiostrepton.  
15 DNA of clones that had lost thiostrepton resistance was analysed by Southern blot hybridisation. Clones in which the DNA encoding the AT12 domain had been replaced by the DNA encoding the AT5 domain was designated *S.*  
*cinamonensis* M12-AT5. At this time individual colonies  
20 were toothpicked onto solid A medium and allowed to grow. Four representative colonies from the A medium plate were grown up in liquid modified YEME medium, which has composition as follows:

Modified YEME medium

25

	Sucrose	100g	
	DIFCO Yeast extract	3g	
	Bacto peptone	5g	
	Oxoid Malt extract	3g	
5	Glucose	10g	-

H<sub>2</sub>O to 1L

pH adjusted to pH 7.2 with NaOH.

These cultures were used to provide a 2% vol/vol inoculum for 30 ml of modified YEME which was grown for 7 days, and then transferred to SM16 medium, which has composition as follows:

SM16 medium

	3-[N-Morpholino]-propane sulfonic	
15	acid (MOPS) buffer	20.9g
	L-proline	10.0g
	Glucose	20g
	NaCl	0.5g
	K <sub>2</sub> HPO <sub>4</sub>	2.1g
20	Ethylenediaminetetraacetic acid,	
	sodium salt	0.25g
	MgSO <sub>4</sub> .7H <sub>2</sub> O	0.49g
	CaCl <sub>2</sub> .2H <sub>2</sub> O	0.029g
	Trace elements solution (Hopwood,	
25	D. A. et al. (1985) Genetic	

Manipulation of *Streptomyces* - a

Laboratory Manual, at p.235)

2 ml

0.5 M CoCl<sub>2</sub> solution

2 microlitres

H<sub>2</sub>O to 1L

5 pH adjusted to pH 7 with NaOH.

After growth for a further 7 days, mycelium was collected by centrifugation at 2000 x g for 30 minutes, and the supernatant was extracted three times with 300 ml of ethyl acetate. To confirm presence of the C-2-ethyl  
10 substituents of both monensin A and B the combined extracts were concentrated by evaporation under reduced pressure to an oil, which was mixed with 1 ml of methanol. Samples were applied to an LCQ liquid chromatograph fitted with a mass spectrometer detector unit. The column used  
15 was a C18 reversed phase column, equilibrated with a mixture of 80% 20mM ammonium acetate/20% acetonitrile, and the column was eluted with a gradient of increasing acetonitrile, reaching 100% acetonitrile over 24 minutes. Mass ions 14 mass units above those expected for both  
20 monensin A and B confirmed production of the respective C-2-ethyl substituents.

Example 7. Construction of pSGK005 and its use in the production of C-13 propyl-erythromycin

Plasmid pSGK005 is a pCJR24 based plasmid containing  
25 a PKS gene comprising a loading module plus the first and

second extension modules and the chain terminating  
thioesterase of the PKS responsible for the production of  
erythromycin (DEBS). The loading module comprises the KS  
and ethyl-malonyl CoA specific AT from module 5 of the  
5 monensin PKS linked to the DEBS loading ACP domain. In  
addition, the active site cysteine of this module 5 KS has  
been mutated to glutamine to convert an extender di-domain  
to a loading di-domain. Plasmid pSGK005 was constructed  
as follows.

10 A 2769bp DNA segment of the monensin cluster of *S.*  
*cinnamomensis* extending from nucleotide 42438 to 45207 was  
amplified by PCR using the following oligonucleotide  
primers. 5'-GTGACGTCATATGTCGAGTGCTGAAGAGTCG-3' and  
5'-GGGGTCGCCTAGGAACCAGCGCCGCCAGTCGA-3'

15 The design of these primers introduced *Nde* I and *Avr*  
II sites at the ends of the amplified fragment. Monensin  
cosmid 05 was used as a template for the reaction. The  
resulting 2769bp fragment was digested with *Nde* I and *Xho*  
I and a 656bp fragment (Fragment A) purified by  
20 preparative gel electrophoresis.

A second PCR reaction was used with the same template  
to amplify DNA from nucleotide 43098 to 45207. The  
primers used were  
5'-CGGCCTCGAGGGCCCGTCGGTCAGTGTGACACGGCGCAGTCCTCCTCGC-3'  
25 and 5'-GGGGTCGCCTAGGAACCAGCGCCGCCAGTCGA-3'

The design of the upstream oligonucleotide primer incorporated a change of the codon specifying the KS active site cysteine (nucleotides 43135-43137, TGC) to glutamine (CAG). The resulting 2109bp DNA fragment  
5 (Fragment B) was digested with *Xho* I and *Avr* II and purified by preparative gel electrophoresis.

Plasmid pCJW80 is derived from pCJR24 and DEBS1-TE in which *Msc* I and *Avr* II sites have been introduced to flank the AT of the DEBS loading module. This plasmid was  
10 digested with *Nde* I and *Avr* II and the larger fragment (Fragment C) purified by preparative gel electrophoresis.

The three fragments (Fragments A, B, C) were ligated together using T4 DNA ligase and the ligation mixture used to transform electrocompetent *E. coli* DH10B cells.  
15 Individual clones were checked for the presence of the desired plasmid pSGK005. The identity of pSGK005 was confirmed by restriction pattern and sequence analysis.

Plasmid pSGK005 was used to transform *S. erythraea* NRRL2338 using a routine protoplast transformation  
20 technique. Thiostrepton resistant colonies were selected on R2T20 media containing g/ml thiostrepton. Further analysis confirmed that pSGK005 had integrated into the *S. erythraea* NRRL2338 chromosome by Southern blot hybridisation of their genomic DNA with DIG-labelled DNA  
25 containing the *actII orf4* promoter. The culture *S.*

erythraea NRRL2338 (pSGK005) was inoculated into 5ml tap  
water medium in a 30ml flask. After three days  
incubation at 29°C this flask was used to inoculate 30ml of  
Ery-P medium in a 300ml flask. The broth was incubated at  
5 29°C at 200rpm for 6 days. After this time the whole broth  
was adjusted to pH8.5 with NaOH, and then extracted twice  
with an equal volume of ethyl acetate. The ethyl acetate  
extract was evaporated to dryness at 45°C under a nitrogen  
stream using a Zymark Turbovap LV evaporator. The product  
10 identities were confirmed by LC/MS. A peak was observed  
with a m/z value of 734 (M+H)<sup>+</sup> required for erythromycin A.  
A second peak was observed with a m/z value of 748 (M+H)<sup>+</sup>,  
required for 13-propyl erythromycin A.

CLAIMS:

1. A DNA sequence which is (a) at least part of the sequence set out in the appended sequence listing; or  
5 (b) a variant of a sequence (a) which encodes a polypeptide which is at least 80%, preferably at least 90%, identical with the corresponding peptide as set out in table II; provided that it is not a sequence encoding all or part of the polypeptide consisting of amino acids  
10 1-920 encoded by mon AI as set out in table II.
2. A DNA sequence according to claim 1 comprising the complete monensin gene cluster or a variant thereof.
- 15 3. A DNA sequence encoding at least part of at least one polypeptide which is necessary for the biosynthesis of monensin, and which is encoded by DNA included in the appended sequence listing or an allele, mutation or other variant thereof; provided that said polypeptide is not  
20 all or part of amino acids 1-920 encoded by mon AI as set out in table II.
4. A DNA sequence according to claim 3 which comprises at least part of one or more of the following  
25 genes: mon BI, mon BII, mon CI, mon CII, mon H, mon RI, mon RII, mon T, mon AIX and mon AX.

5. A DNA sequence according to claim 4 comprising all of the genes listed therein or an allele, mutation or other variant thereof.

5 6. A DNA sequence according to claim 3 encoding at least part of one or more of the polypeptides set out below, said polypeptide having the amino acid sequence as set out in the appended sequence data or being a variant thereof having the specified activity:

10	<u>peptide</u>	<u>activity</u>
	mon CII	epoxyhydrolase/cyclase
	mon E	S-adenosylmethionine-dependent methyltransferase
	mon T	monensin resistance gene
	mon RII	repressor protein
15	mon AIX	thioesterase
	mon AI	polyketide synthase multienzyme
	mon AII	polyketide synthase multienzyme
	mon AIII	polyketide synthase multienzyme
	mon AIV	polyketide synthase multienzyme
20	mon AV	polyketide synthase multienzyme
	mon AVI	polyketide synthase multienzyme
	mon AVII	polyketide synthase multienzyme
	mon AVIII	polyketide synthase multienzyme
	mon H	regulatory protein
25	mon CI	flavin-dependent epoxidase
	mon BII	carbon-carbon double bond isomerase

*mon BI* carbon-carbon double bond isomerase  
*mon D* cytochrome P450 hydroxylase  
*mon RI* activator protein  
*mon AX* thioesterase

5

7. A DNA sequence according to claim 6 encoding a single enzyme activity of a multienzyme encoded by any of *mon AI-mon AVIII* or a variant or part thereof.

10

8. A DNA sequence according to any preceding claim encoding any one or more of the domains as set out in Table I or a variant or part thereof.

15

9. A DNA sequence according to any preceding claim which has a length of at least 30, preferably at least 60, bases.

20

10. A recombinant cloning or expression vector comprising a DNA sequence according to any preceding claim.

25

11. A transformant host cell which has been transformed to contain a DNA sequence according to any of claims 1-9 and which is capable of expressing a corresponding polypeptide.

12. A hybridisation probe which is a DNA sequence according to any of claims 1-9.

13. Use of a probe according to claim 12 to detect a  
5 PKS cluster, optionally followed by isolation of the detected cluster.

14. Use of a probe according to claim 12 which encodes at least part of a polypeptide having a known  
10 function to detect genes encoding polypeptides having analogous function.

15. Use according to claim 14 wherein the polypeptide of known function is AT of module 5 or the  
15 regulatory protein encoded by *mon RI*.

16. A hybridization probe comprising a polynucleotide which binds specifically to a region of the monensin gene cluster selected from *mon BI*, *mon BII*, *mon CI*, *mon CII*, *mon H*, *mon RI*, *mon RII*, *mon T*, *mon AIX* and  
20 *mon AX*.

17. Use of a probe according to claim 16 in a method of detecting the presence of a gene cluster which governs  
25 the synthesis of a polyether, and optionally isolating a gene cluster detected thereby.

18. Use of a probe according to claim 12 which  
comprise a polynucleotide which binds specifically to a  
gene responsible for levels of activity of the monensin  
gene cluster, in a method of detecting an analogous gene  
5 in a gene cluster for biosynthesis of another polyketide,  
optionally followed by a step of manipulating the gene  
detected thereby to alter the level of expression of said  
other polyketide.

10 19. Use according to claim 18 wherein the gene is a  
regulatory gene, resistance gene or thioesterase gene.

20. Use of the *mon RI* gene or variant and a monensin  
promoter to control expression of a heterologous gene in  
15 *S. cinnamonensis*.

21. Use of a portion of the monensin gene cluster  
encoding a polypeptide having chain terminating activity,  
preferably comprising at least one of *mon AIX* and *mon AX*  
20 or a mutant, allele or other variant thereof encoding a  
polypeptide having chain terminating activity, to effect  
chain release of a peptide other than monensin.

22. Use of a portion of the monensin gene cluster  
25 encoding a polypeptide having carbon-carbon double bond  
isomerase activity, preferably comprising at least one of

*mon BI* and *mon BII* or a mutant, allele or other variant thereof having isomerase activity to provide a desired stereochemical outcome in the synthesis of a polyketide other than monensin.

5

23. A polypeptide encoded by a portion of the monensin gene cluster, preferably comprising at least one of *mon BI* and *mon BII* or a mutant, allele or other variant thereof, having carbon-carbon double bond isomerase activity, or at least one of *mon AIX* and *mon AX* or a mutant, allele or other variant thereof having chain terminating activity.

10

24. An epoxidase enzyme encoded by *mon CI* or a derivative or variant thereof having epoxidase activity.

15

25. A cyclase enzyme encoded by *mon CII* or a derivative or variant thereof having cyclase activity.

20

26. Use of a portion of the monensin gene cluster encoding a peptide having epoxidase or cyclase activity, preferably comprising *mon CI* or *mon CII* or a mutant, allele or other variant thereof encoding a polypeptide having epoxidase or cyclase activity to provide a said activity in the biosynthesis of a polypeptide other than monensin.

25

27. A process for producing a polyketide containing a desired starter unit comprising providing a PKS gene having a loading module and a plurality of extension modules, wherein the loading module includes a KS<sub>q</sub> domain  
5 derived from a KS domain of a monensin extension module.

28. A process according to claim 27 wherein the KS<sub>q</sub> domain is derived from KS of module 5 of monensin.

10 29. A process according to claim 27 or claim 28 wherein the starter unit also includes an AT<sub>q</sub> domain derived from an AT domain which is naturally associated with the KS domain.

15 30. A DNA sequence comprising DNA encoding at least one PKS loading module and a plurality of PKS extension modules, and which can be expressed to produce a polyketide; wherein at least one of said modules or at least one domain thereof is a monensin module or domain or  
20 a variant thereof and is contiguous to a further one of said modules or a domain to which it is not naturally contiguous; provided that the sequence is not an ery loading module, the first and second extension modules of the ery PKS and the ery chain-terminating thioesterase in  
25 which the DNA encoding AT of the first extension module has been substituted by DNA encoding an ethyl malonyl-CoA

AT from the monensin gene cluster.

31. A DNA sequence according to claim 30 wherein  
said further module or domain is also a monensin module or  
5 domain or variant thereof.

32. A DNA sequence according to claim 30 wherein  
said further module or domain is a module or domain of a  
PKS of a polyketide other than monensin or a variant  
10 thereof.

33. A DNA sequence according to claim 30, 31 or 32  
wherein said loading module is adapted to load a starter  
unit other than a starter unit normally received by the  
15 adjacent extension module.

34. A DNA sequence according to claim 33 wherein  
said loading module is derived from a monensin extension  
module or variant thereof.

20

35. A polyketide synthase encoded by the DNA  
sequence of any of claims 30-34.

36. A polyketide compound as produced by a synthase  
25 according to claim 35.

37. A vector containing a DNA sequence of any of claims 30-34.

38. A transformant cell transformed to contain a DNA sequence of any of claims 30-34.

39. A method of producing *S. cinnamonensis* capable of enhanced levels of production of monensin comprising engineering it to overexpress the *mon RI* gene.

10

40. A method according to claim 39 wherein said engineering comprises introducing at least one additional copy of the *mon RI* gene as shown in the appended sequence data or a variant thereof.

15

41. *S. cinnamonensis* containing multiple copies of the *mon RI* gene as shown in the appended sequence data and/or variant(s) thereof.

20

42. A method of producing monensin comprising culturing the organism of claim 41 and/or an organism produced by the method of claim 39 or claim 40.

25

43. A process for expressing a gene heterologous to *S. cinnamonensis* comprising transforming *S. cinnamonensis* with DNA encoding a heterologous gene and expressing said

gene under control of the activator gene *mon RI* or  
*actII/orf4*.

44. A process according to claim 43 wherein said  
5 heterologous gene is a PKS gene.

45. 13-Propyl erythromycin A.

monensin A : R = ethyl  
monensin B : R = methyl

**BUDAPEST TREATY ON THE INTERNATIONAL  
RECOGNITION OF THE DEPOSIT OF MICROORGANISMS  
FOR THE PURPOSES OF PATENT PROCEDURE**

Professor P.F. Leadlay,  
Department of Biochemistry,  
University of Cambridge,  
80 Tennis Court Road,  
Cambridge.  
CB2 1GA

**INTERNATIONAL FORM**

**RECEIPT IN THE CASE OF AN ORIGINAL DEPOSIT**  
issued pursuant to Rule 7.1 by the  
**INTERNATIONAL DEPOSITARY AUTHORITY**  
identified at the bottom of this page

NAME AND ADDRESS  
OF DEPOSITOR

<b>I. IDENTIFICATION OF THE MICROORGANISM</b>	
Identification reference given by the DEPOSITOR:  <i>Escherichia coli</i> XL1-Blue MR (MO-CN11) 7	Accession number given by the INTERNATIONAL DEPOSITARY AUTHORITY:  NCIMB 40956
<b>II. SCIENTIFIC DESCRIPTION AND/OR PROPOSED TAXONOMIC DESIGNATION</b>	
The microorganism identified under I above was accompanied by:  <input type="checkbox"/> a scientific description  <input checked="" type="checkbox"/> a proposed taxonomic designation  (Mark with a cross where applicable)	
<b>III. RECEIPT AND ACCEPTANCE</b>	
This International Depositary Authority accepts the microorganism identified under I above, which was received by it on 1 July 1998 (date of the original deposit) <sup>1</sup>	
<b>IV. RECEIPT OF REQUEST FOR CONVERSION</b>	
The microorganism identified under I above was received by this International Depositary Authority on (date of the original deposit) and a request to convert the original deposit to a deposit under the Budapest Treaty was received by it on (date of receipt of request for conversion)	
<b>V. INTERNATIONAL DEPOSITARY AUTHORITY</b>	
Name: NCIMB Ltd.,  Address: 23 St Machar Drive, Aberdeen, AB24 3RY, Scotland.	Signature(s) of person(s) having the power to represent the International Depositary Authority or of authorised official(s):  Date: 9 July 1998

<sup>1</sup> Where Rule 6/4(d) applies, such date is the date on which the status of International Depositary Authority was acquired.  
Form BP/4 (sole page)

**BUDAPEST TREATY ON THE INTERNATIONAL  
RECOGNITION OF THE DEPOSIT OF MICROORGANISMS  
FOR THE PURPOSES OF PATENT PROCEDURE**

Professor P.F. Leadlay,

**INTERNATIONAL FORM**

**RECEIPT IN THE CASE OF AN ORIGINAL DEPOSIT**  
issued pursuant to Rule 7.1 by the  
**INTERNATIONAL DEPOSITARY AUTHORITY**  
identified at the bottom of this page

NAME AND ADDRESS  
OF DEPOSITOR

**I. IDENTIFICATION OF THE MICROORGANISM**

Identification reference given by the  
DEPOSITOR:

*Escherichia coli*  
XL1-Blue MR (MO-CN02)

Accession number given by the  
INTERNATIONAL DEPOSITARY AUTHORITY:

NCIMB 40958

**II. SCIENTIFIC DESCRIPTION AND/OR PROPOSED TAXONOMIC DESIGNATION**

The microorganism identified under I above was accompanied by:

☐

a scientific description

☒

a proposed taxonomic designation

(Mark with a cross where applicable)

**III. RECEIPT AND ACCEPTANCE**

This International Depositary Authority accepts the microorganism identified under I above, which was received by it on  
1 July 1998 (date of the original deposit)<sup>1</sup>

**IV. RECEIPT OF REQUEST FOR CONVERSION**

The microorganism identified under I above was received by this International Depositary Authority on  
(date of the original deposit) and a request to convert the original deposit to a deposit under the Budapest Treaty was received by it on  
(date of receipt of request for conversion)

**V. INTERNATIONAL DEPOSITARY AUTHORITY**

Name: NCIMB Ltd.,

Address: 23 St Machar Drive,  
Aberdeen,  
AB24 3RY,  
Scotland.

Signature(s) of person(s) having the power to represent the  
International Depositary Authority or of authorised  
official(s):

Date: 9 July 1998

<sup>1</sup> Where Rule 6/4(d) applies, such date is the date on which the status of International Depositary Authority was acquired.

# INTERNATIONAL SEARCH REPORT

International Application No  
PCT/GB 00/02072

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 C12N15/52 C12N15/76 C12P17/18 C12P19/44 C12P19/62  
C12Q1/68 C07H17/08 C07H19/01

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 C12N C12P C12Q C07H

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, MEDLINE, STRAND, EMBL, BIOSIS, EMBASE, WPI Data, PAJ, CHEM ABS Data

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	DONOVAN M J ET AL.: "Isolation of DNA involved in monensin biosynthesis by <i>Streptomyces cinnamonensis</i> ;" ABSTR. ANNU. MEET. AM. SOC. MICROBIOL. 88 MEET., 1988, page 261 XP000949887	1-3,6-14

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"Z" document member of the same patent family

# INTERNATIONAL SEARCH REPORT

International application No.  
PCT/GB 00/02072

## Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

see further information sheet invention 1

### Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1,8-12,14,43,44 (all partially); 2-7,13,15-42, 45 (all completely)

A DNA sequence comprising the complete monensin (mon) gene cluster, or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with one of the peptides according to SEQ ID NOs 12-33 (AcpX to MonAX as set out in table II), provided that said polypeptide is not all or part of amino acid 1-920 encoded by monAI. Vectors, transformed cells, hybridization probes and their uses.

Use of mon genes to control expression (monRI), to effect chain release (monAIX and monAX), to provide a desired stereochemical outcome (monBI and monBII), or to provide epoxidase or cyclase activity (monCI and monCII). Mon polypeptides having isomerase activity (MonBI and MonBII), or having chain terminating activity (MonAIX or MonAX), or having epoxidase activity (MonCI), or having cyclase activity (MonCII).

Processes for producing polyketides involving monensin loading or extension modules or domains. DNA sequences encoding hybrid polyketide synthases containing one or more monensin modules or domains (provided that it is not encoding an ery loading module, the first and second ery extension modules and the ery chain-terminating thioesterase in which the AT domain of the first ery extension module has been substituted by the ethyl malonyl-CoA AT from the monensin synthase), polyketide synthases encoded by said DNA sequences, and polyketide compounds produced by said polyketide synthases. Vectors and transformed cells.

Methods of producing *S. cinamonensis* capable of producing enhanced levels of monensin by overexpressing or amplifying the monRI gene, *S. cinamonensis* strains produced thereby, and use of said strains in monensin production.

Process for expressing a heterologous gene, e.g., a PKS gene, in *S. cinamonensis* under the control of monRI.

2. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:5 (GdhA as set out in table II), vectors, transformed cells, hybridization probes and their uses.

3. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:6 (DapA as set out in table II), vectors, transformed cells, hybridization probes and their uses.

4. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:7 (Orf3 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

5. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:8 (Orf4 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

6. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:9 (Orf5 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

7. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:10 (Orf6 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

8. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:11 (Orf7 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

9. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:34 (Orf29 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

10. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:35 (LipB as set out in table II), vectors, transformed cells, hybridization probes and their uses.

11. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:36 (Orf31 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

12. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:37 (Orf32 as set out in table II), vectors, transformed cells, hybridization probes and their uses.

13. Claims: 1,8-12,14 (all partially)

A DNA sequence or a part or a variant of it which encodes a polypeptide (or part of it) which is at least 80%, preferably at least 90% identical with a peptide according to SEQ ID NO:38 (AmtA as set out in table II), vectors, transformed cells, hybridization probes and their uses.

14. Claims: 43,44 (both partially)

Process for expressing a heterologous gene, e.g., a PKS gene, in *S. cinnamomensis* under the control of actII/orf4.
